

Final Project Pharse II

Java SSM Based Online Shopping Website

Team members:

Zeyu Pan (615) Email: zpan8@jhu.edu

Chen Wang (615) Email: cwang129@jhu.edu

Shanshan Yang (615) Email: syang91@jhu.edu

Our project is online shopping website with data acquired from <https://www.tmall.com/>, which supports all the major functions of any shopping websites, such as user register, login, logout, list products by category, search by keyword, check product in detail and it also implements the entire process of shopping, like add to cart, checkout, generate orders, keep track of orders, review products. Users can browse items according to overall score (asc or desc), post time (asc or desc), popularity (asc or desc), price (asc or desc), sold amount (asc or desc) and price range. Users can also see item details and place order.

How to see result : You can see the result from our demo:

<https://drive.google.com/drive/my-drive>

or see from part 6 Project demonstration and summerization

Main Body

1. How the data loaded and related code for processing, extracting or loading:

We collect the data from Chinese famous online shopping website Tmall: <https://www.tmall.com/> and inspect Element using google chrome to parse html and find the link address, header, query conditions, and in some special conditions using cookie files to get Jsonp data, and convert it into Json format and subtract it and save the data into excel. Also subtract the link of images and save the link to excel. After processing read and load the data from excel to my sql database.

Code implementation in python:

```
def getHtml(url,daili='',postdata={}):  
  
    """  
  
    crawler website: support cookie  
  
    the first parameter is website, the seconde parameter is POST data  
  
    """  
  
    # COOKIE file path  
  
    filename = 'cookie.txt'  
  
    # declare a MozillaCookieJar object and save it into file  
  
    cj = http.cookiejar.MozillaCookieJar(filename)  
  
    # read the content of cookie from file  
  
    # ignore_discard means save cookies even if it will be abandoned soon  
  
    # ignore_expires means if the cookies is already exist in the  
  
    # file, override it
```

```

# if exist, then read main COOKIE

if os.path.exists(filename):

    cj.load(filename, ignore_discard=True, ignore_expires=True)

# read other COOKIE

if os.path.exists('../subcookie.txt'):

    cookie = open('../subcookie.txt', 'r').read()

else:

    cookie='ddd'

# build proxy support with cookie handker

proxy_support = urllib.request.ProxyHandler({'http':'http://'+daili})

# open proxy support

if daili:

    print('proxy:'+daili+'open')

    opener = urllib.request.build_opener(proxy_support,
urllib.request.HTTPCookieProcessor(cj), urllib.request.HTTPHandler)

else:

    opener =
urllib.request.build_opener(urllib.request.HTTPCookieProcessor(cj))

# open header

opener.addheaders = [('User-Agent',

```

```
        'Mozilla/5.0 (iPad; U; CPU OS 4_3_3 like Mac OS  
X; en-us) AppleWebKit/533.17.9 (KHTML, like Gecko) Version/5.0.2 Mobile/8J2  
Safari/6533.18.5'),
```

```
        ('Referer',  
  
         'http://s.m.taobao.com'),  
  
        ('Host', 'h5.m.taobao.com'),  
  
        ('Cookie', cookie)]
```

```
# dispatch opener
```

```
urllib.request.install_opener(opener)
```

```
# if data need POST
```

```
if postdata:
```

```
    # data URL encoding
```

```
    postdata = urllib.parse.urlencode(postdata)
```

```
    # crawler html
```

```
    html_bytes = urllib.request.urlopen(url, postdata.encode()).read()
```

```
else:
```

```
    html_bytes = urllib.request.urlopen(url).read()
```

```
# save COOKIE into file
```

```
cj.save(ignore_discard=True, ignore_expires=True)
```

```
return html_bytes
```

2. User guide

Getting Started

Just like building many other Java projects, before running it, you need to install Java and a suitable IDE on our PC.

Prerequisites

Firstly, you need to install Java JDK, JRE and set some environmental variables on your operating system. Here are some Java install instructions.

[Install Java JDK in Windows](#)

[Install Java JDK in Ubuntu](#)

The next step is to select an IDE, I recommend you to use Eclipse or IntelliJ IDEA. Here are the links of their download page.

[Download Eclipse](#)

[Download IntelliJ IDEA](#)

Installing

After copying the project on your local machine, you need to add it into your IDE as a project.

The process is simple. Take IntelliJ IDEA as an example, click File->Open File or Project, select the "pom.xml" file under the main folder, which allows the IDE to open the project with Maven.

To run the project, you need to install Maven at first:

[Install maven in Windows](#)

[Install maven in Ubuntu](#)

Next in the Run/Debug configuration page, you must add a maven builder.

As for the maven builder, you should set the setting file and repository as the folder where you install the maven, like:

```
mavenFolder\.m2\settings.xml  
mavenFolder\.m2\repository
```

You should use tomcat as server and set it listening to the 8080 port as default. To start the server, you can set the command line parameter as:

```
tomcat7:run
```

Once you start the server, you can visit the home page by typing the URL below on your browser:

```
http://localhost:8080/tmall_ssm/home
```

3. Major areas of specialization

- (1) **Complex extraction of real data from online sources:** We extract the product information from the real shopping website Tmall using the web crawler technique and preprocess the data to present their attributes and relationship with 9 database tables.
- (2) **Original and challenging data modeling:** After preprocessing the data, there are 9 tables. For example, the Product table contains the features of each product like its id, name, original price, promote price and stock number and its category id. Another table is the category table which contains its id and name. So there exists a many to one relationship between category and products, that for one category it has multiple products while each product belongs to one category.
- (3) **Transaction Control:** Our transaction control allows concurrent read but for writing operation like user writing comments, adding products into the cart and checkout, in order to keep the data consistent, we set the level of consistency as repeatable read that is only the committed records to be read, repeated reads of same record must return same value. However, a transaction may not be serializable, it may find some records inserted by a transaction by a transaction but not find others.

4. Project Strengths and selling points

Technology Stack

SMM framework

In this project we integrate three popular frameworks, Spring, Spring MVC and Mybatis, which greatly shorten the time to develop a project.

Spring framework

- (1) We use its ability of Inversion of Control to let Spring take over the relation control between objects, which reduce the coherence and shorten the period of development.
- (2) Using the ability of Aspect oriented programming to support database transaction, log and privilege control.

Spring MVC framework

- (1) Compatible with Spring framework
- (2) It is convenient to deal with data, for example data authentication, data format and data binding mechanism.

MyBatis framework

- (1) We write the SQL statement inside the XML which is much easier to control and optimize, and it lowers the degree of coupling between Java code and SQL.
- (2) It supports tag mapping and can map attributes in class and features in database.
- (3) It supports dynamic SQL editing.

MyBatis Generator

MyBatis Generator is a code generator for MyBatis. It can generate code for all versions of MyBatis. I can generate several classes based on the features of data in database. As a result, we don't need to create data or configuration file when we try to modify or access to data. MyBatis implements most of simple database operations like CRUD(Create, Retrieve, Update, Delete), while for complex operations including join queries and stored procedure, we still need to write SQL code by hand.

MyBatis Generator can generate:

- (1) Java POJO classes matching the structure of database tables, which includes:
 - (a) a class to match the primary key of the table.
 - (b) a class to match the non-primary key fields of the table.
 - (c) a class to enable dynamic selects, updates, and deletes

There exists inheritance relationship between several classes, Using generator with different configuration we can generate different structure of inheritance levels.

- (2) MyBatis is compatible for SQL mapping XML files. It can generate SQL of CRUD operations for all the tables, which includes:
 - (a) update by primary key

- (b) update by example (using a dynamic where clause)
- (c) delete by primary key
- (d) delete by example (using a dynamic where clause)
- (e) select by primary key
- (f) select by example (using a dynamic where clause)
- (g) count by example

Based on the structure of table, the generated SQL may vary like if the table does not possess primary key, there will not be a method named update by primary key.

Code Structure

Back-End

The backend is implemented with Java and all the codes are under the org.pzy.tmall source directory. According to their function and responsibility, they are distributed into 6 sub-directories.

- controller : all the Spring MVC controllers, which directly handle the HTTP request.
- interceptor: check user login status, being called before requests are handled by controller.
- mapper: a series of interfaces, used to execute SQL command defined in .xml files to CRUD data.
- pojo: all the data types, which are in accord with the data defined in database.
- service: define several APIs called by controller, handle business logic by using the method in mapper.
- util: several utilities to process special kinds of data like uploaded images.

Front-End

All the frontend codes are written in .jsp files with Java, Vue.js, HTML, Bootstrap and jQuery. They are distributed in three main folders ;

- admin: all the codes of data management pages, which are only accessible for administrators.
- fore: the pages visible for all normal customers.
- include: some pages that are integrated into the pages in previous folders, and some shared pages like head and foot.

Built With

- Spring, MyBatis, Spring MVC- The back-end web framework used
- Vue.js, jQuery, Bootstrap- The front-end web framework used
- Maven - Dependency Management

5. Project limitations, improvements and extensions

- 1) The limitations for our project is that because all the data we acquired are from a Chinese website, all the data are written in Chinese, which is hard for foreigners to read and get use it. If we are given additional time, we will also make an all English version website and convert all the files and data into English.
- 2) For back-end, we can add an administrator module and subdivide the rights to several levels and give rights to administrator and let them maintain the website based on their leaves.
- 3) We can also add a feature to sort the picture base on different categories like colour, seller etc.
- 4) Add the function to allow user to use coupon or red package to save money

6. Project demonstration and summerization

DEMO: <https://drive.google.com/drive/my-drive>

PS: Translation and commont for Chinese are witten in **red color**.

Appendix

DataBase Final Project Proposal

1. Shanshan Yang, Zeyu Pan, Chen Wang (With prior approval teams of 3)
2. Our database contains the data of a shopping website. It consists of the data of products, properties, categories, users, orders and order items so on and so forth.
3.
 - (1) Compute the number of products for each category.
 - (2) List all the products in television category with prices less than 1000\$.
 - (3) Compute the average prices of products in each product categories.
 - (4) Get the most viewed products in the past six months.
 - (5) Calculate the number of clothes in each different size.
 - (6) Return all the products with name containing a specific search word.
 - (7) Sort a list of products in the same category based on their prices.
 - (8) Sort a list of products in the same category based on their viewed number.
 - (9) List all the orders the user have submitted.
 - (10) Calculate the sum of saving money for a specific user in the past one year.
 - (11) Get the most products for one user having bought.
 - (12) From all the product the user having bought, get the product with highest price.
 - (13) Return the number of products in each of orders.
 - (14) List the total number of products of one category.
 - (15) List the user with sailing address in the same state.
4. Design and show a relational data model

                                GROUP BY orders.oid)

```

6. Plan to load the databases:

We go through the website of Tmall online shopping platform and crawler data from this website <https://www.tmall.com/> by parsing the html tags and store them into xml format files. Then we design relations and tables according to these data. The issues that we expected to encounter is that the raw data that we crawled need to reformat and reduce the redundancy to better fit our database.

7. The result that we plan to generate:

For our databases final project, we want to build an online shopping website, which contains some similar functions as Amazon or eBay. More specific, it is a Java web project which imitates the famous Chinese online shopping website Tmall. It will support all the major functions of any shopping websites, such as user register, login, logout, list products by category, search by keyword, check product in detail and it also implements the entire process of shopping, like add to cart, checkout, generate orders, keep track of orders, review products so on and so forth. For implementation, we want to use Vue.js, JQuery and AJAX.

8. The specialized / advanced topics that we plan to focus on in the database is:

- Security - Shiro (for payment)
- Object-oriented database design / implementation
- Advanced SQL topics - myBatis, JDBC
- data mining
